Executive Summary

Million Hearts® is a U.S. Department of Health and Human Services initiative, co-led by the Centers for Disease Control and Prevention (CDC) and the Centers for Medicare & Medicaid Services (CMS), with the goal of preventing one million heart attacks and strokes by 2017. To help achieve this goal, Million Hearts® aims to increase by 10 million the number of people in the United States whose blood pressure is under control.1

Self-measured blood pressure monitoring (SMBP) plus additional clinical support* is one strategy that can reduce the risk of disability or death due to high blood pressure. SMBP is defined as regular measurement of blood pressure by the patient outside the clinical setting, either at home or elsewhere. It is sometimes called “home blood pressure monitoring.” Additional clinical support includes regular one-on-one counseling, Web-based or telephonic support tools, and educational classes and is further defined on page 9.

This guide provides action steps and resources on SMBP for clinicians and is not meant to replace individual clinical judgment. It includes the following elements:

- Action steps clinicians can take to implement SMBP plus additional support.
- A description of the burden of hypertension.
- A summary of the scientific evidence establishing the significance and effectiveness of SMBP plus additional support.
- An explanation of additional support strategies for SMBP.
- Types and costs of home blood pressure monitors used for SMBP.
- Current health insurance coverage for SMBP.

The purpose of this guide is to facilitate the implementation of SMBP plus clinical support in four key areas: preparing care teams to support SMBP, selecting and incorporating clinical support systems, empowering patients, and encouraging health insurance coverage for SMBP plus additional clinical support. For each area, the guide lists actions that can facilitate the implementation of SMBP plus additional support. Beside each action step, it provides corresponding electronic resources to assist with these actions. It also includes appendices that describe proper SMBP preparation and technique, clinical support interventions that are effective when used with SMBP, the proper way to check a home blood pressure monitor for accuracy, and the burden and cost of hypertension.

* In July 2012, the Agency for Healthcare Research and Quality (AHRQ) published a comparative effectiveness review of SMBP. The only finding with strong evidence of effectiveness was the implementation of SMBP with additional clinical support; that is, evidence was not sufficient to support SMBP alone as an effective intervention for improving blood pressure.
Self-Measured Blood Pressure Monitoring

Definition and Indications

SMBP plus additional clinical support is one alternative to traditional office care that could improve access to care and quality of care for individuals with hypertension while making blood pressure control more convenient and accessible across the population. SMBP, or home blood pressure monitoring, is the regular measurement of blood pressure by a patient at home or elsewhere outside the clinic setting using a personal home measurement device. A Joint Scientific Statement from the American Heart Association (AHA), American Society of Hypertension (ASH), and Preventive Cardiovascular Nurses Association (PCNA) encourages increased regular use of SMBP by clinicians for the majority of patients with known or suspected hypertension as a way to increase patients’ engagement and ability to self-manage their condition, enabling the care team to assist in timely achievement and maintenance of control and preventing heart attacks and strokes. It further states that SMBP may be particularly useful in certain types of patients, including the elderly, people with diabetes or chronic kidney disease, pregnant women, and those with suspected or confirmed white coat hypertension.

A Joint Scientific Statement from AHA, ASH, and PCNA encourages increased regular use of SMBP by clinicians for the majority of patients with known or suspected hypertension as a way to increase patients’ engagement and ability to self-manage their condition. Although public education campaigns can encourage patients to monitor their blood pressure at home, clinician support is critical for empowering patients, training them on proper measurement techniques, monitoring home readings, and providing timely advice on needed medication titrations and lifestyle changes.

Action Steps for Clinicians

Clinicians are key to the widespread implementation of SMBP plus additional clinical support. Although public education campaigns can encourage patients to monitor their blood pressure at home, clinician support is critical for empowering patients, training them on proper measurement techniques, monitoring home readings, and providing timely advice on needed medication titrations and lifestyle changes. This guide provides a comprehensive plan and resources for clinicians who want to support SMBP in their practices and health care systems. Figure 1 lists evidence-based strategies that clinicians can use to implement a comprehensive SMBP initiative. The strategies are organized into four categories of actions:

- Preparing care teams to engage patients in SMBP (Table 1)
- Selecting and incorporating clinical support systems for SMBP (Table 2)
- Empowering patients to use SMBP (Table 3)
- Encouraging coverage for SMBP plus additional clinical support (Table 4)

By incorporating all of these strategy types into their workflow, clinicians can make SMBP a seamless part of routine care for patients with hypertension.
Figure 1. Steps to Implementing a Comprehensive SMBP Program

**Prepare Care Teams to Support SMBP**
- Standardize training
- Understand laws and regulations
- Train relevant members of the care team
- Standardize treatment

**Select and Incorporate Clinical Support Systems**
- Use an existing model
- Establish a feedback loop
- Reach out to partners with health information technology (HIT) expertise

**Empower Patients to Use SMBP**
- Discuss BP and SMBP
- Choose device
- Check accuracy
- Provide SMBP training
- Provide written guidance
- Choose a BP tracking method
- Subsidize device

**Encourage Payer Coverage of SMBP**
- Understand health plan reimbursement
- Collaborate with partners
- Understand laws and regulations

Burden of Hypertension

Prevalence and Consequences of Hypertension

Hypertension is the most common reason for a person with any chronic condition to visit a clinician, and it is a major risk factor for heart disease, stroke, and kidney disease. Even small increases in blood pressure increase the risk for cardiovascular disease and mortality; the risk of death from ischemic heart disease and stroke doubles for every 20 mmHg increase in systolic blood pressure (SBP) or 10 mmHg increase in diastolic blood pressure (DBP). Hypertension affects almost one-third of American adults aged 18 or older (72 million people) and is uncontrolled in nearly half of those (35 million people). This population with uncontrolled hypertension represents a large pool of patients for whom clinicians could consider further clinical intervention, including SMBP. For more information on the burden and cost of hypertension, see Appendix D.

Replacing some face-to-face primary care visits with other forms of care, such as electronic and phone communication, could make care safer and more effective, patient-centered, timely, and efficient. Electronic, telephonic, and other forms of non-face-to-face communication also may allow clinicians to spend more of their time improving the quality of the face-to-face visits that do occur.

Traditional office-based and fee-for-service models of health care delivery and payment reimburse clinicians only for office-based visits and services. Thus, new delivery and care models, such as patient-centered medical homes, ACOs, and bundled/episode-based payments, are needed. These models may provide opportunities for health plans to promote SMBP plus clinical support interventions through unique features such as incentives, care management fees, and shared savings/risk tied to performance on quality measures. For SMBP interventions to be successful at a population level, clinicians must have innovative methods to streamline data into user-friendly reports so they can focus care delivery.

Evidence for SMBP Plus Additional Clinical Support

A 2012 comparative effectiveness review by AHRQ examined the effectiveness of SMBP alone compared to SMBP plus additional support to usual care. Patients using SMBP at home only took readings themselves or had a caretaker take them. They then shared the readings with...
AHRQ found strong evidence that SMBP plus additional clinical support was more effective than usual care in lowering blood pressure and improving control among patients with hypertension. In the studies AHRQ examined, all six “quality A” trials reported statistically significant reductions in blood pressure among patients using SMBP plus additional support (see Appendix B for a detailed table of select effective clinical support interventions). The mean net reduction in SBP ranged from 3.4 to 8.9 mmHg, and the mean net decrease in DBP ranged from 1.9 to 4.4 mmHg at up to 12 months follow-up.27–32

Additional Clinical Support Strategies for SMBP
The type of additional support in the studies AHRQ examined varied widely but fell into three main categories: regular one-on-one counseling,7,28,29,31,33,34 Web-based or telephonic support tools that did not involve face-to-face interaction,27,30–32,35,36 and educational classes.29,37,38

▷ One-on-one counseling: Examples included regular telephone calls from nurses to manage blood pressure–lowering medication7 and in-person counseling sessions with trained pharmacists.34

▷ Web-based or telephonic support: Examples included an interactive computer-based telephone feedback system30 and secure patient website training plus pharmacist care management delivered through Web communications,31 both in response to patient-reported blood pressure readings.

▷ Educational classes: Examples included telephone-based education by nurses on blood pressure–lowering behaviors, delivered only when patients reported poor blood pressure readings,29 and small-group classes on SMBP technique and lifestyle changes that help lower blood pressure, taught by PAs.37

More research is needed to determine whether one form of support is most effective.2 However, with one exception, all forms of additional support in the trials that successfully lowered patients’ blood pressure were administered by clinicians (e.g., pharmacists, NPs, PAs) specifically

Many different kinds of SMBP plus additional support interventions have successfully lowered blood pressure in patients with hypertension. Common elements of successful SMBP plus additional support interventions for patients are:2,27–38:

▷ Delivery of intervention by trained clinicians (e.g., pharmacists, NPs, PAs, health educators).

▷ Regular patient communication of SMBP readings to clinicians.

▷ A patient/clinician “feedback loop” in which clinician support and advice are customized based on patients’ reported information (see Figure 2).
When SMBP is done at home, it could help reduce hypertension-related disparities among vulnerable populations because clinicians can collect information about patients’ blood pressure, medications, and health behaviors without requiring them to pay for and travel to a doctor’s office for every blood pressure reading.7,27–32,35,37

If maintained over time, interventions using SMBP plus additional support could contribute to improved blood pressure control for many patients with hypertension. The delivery and components of successful SMBP plus additional clinical support interventions vary widely, and this flexibility may mean clinicians can implement interventions across numerous health care settings and patient populations. However, more formal evaluation of these approaches is needed.

Figure 2.

- Suggestions to achieve lifestyle changes
- Actions to sustain or improve adherence
- Advice about community resources to assist in controlling blood pressure

Clinician
Some studies suggest that when SMBP is done at home, it could help reduce hypertension-related disparities among vulnerable populations because clinicians can collect information about patients’ blood pressure, medications, and health behaviors without requiring them to pay for and travel to a doctor’s office for every blood pressure reading.\textsuperscript{7,27–32,35,37} One challenge is the current requirement that clinicians deliver services in person to be reimbursed. This may become less of an issue as payment models transition from fee-for-service to pay-for-value. See Table 7 for information on current coverage.

**Home Blood Pressure Monitors and Cuffs Used for SMBP**

Available home blood pressure monitors range from manual (auscultatory) devices to partially or fully automated (oscillometric) devices.\textsuperscript{39} Automated devices require less skill than manual devices, are widely available, and are likely to reduce the risk of error in home blood pressure measurements.\textsuperscript{3,39} Although upper arm, wrist, and finger monitors are available, upper arm monitors are recommended by AHA, ASH, and PCNA, among others, for accuracy of measurement.\textsuperscript{39}

Patients should expect to pay in the range of $50 to $100 for an accurate upper arm home blood pressure monitor.\textsuperscript{3,40} Wrist cuffs may be used as an alternative for patients who are obese or have other difficulties using upper arm cuffs, but the accuracy of readings may be inconsistent.\textsuperscript{1} Finger cuffs are not accurate and should not be used.\textsuperscript{3,39}

For a summary of preferred home blood pressure monitor features, see Table 5.

To choose the best option for the patient, consider:

- Preferred monitor characteristics (Table 5).
- Cuff size measurement (Table 6).
- Insurance coverage (Table 7).

Clinicians should encourage patients to bring home blood pressure monitors in for comparison with in-office readings taken by a trained clinician (see Appendix C for detailed instructions). Such visits are also a good opportunity to educate patients and their family members about the proper use of their SMBP devices (see Appendix A). Patients with atrial fibrillation or other types of irregular heartbeat (arrhythmias), as well as those with certain physical or mental conditions, may have difficulty taking accurate readings using automated home blood pressure monitors.\textsuperscript{3} However, this does not mean that

* Wrist cuffs may be used as an alternative for patients who are obese or have other difficulties using upper arm cuffs, but the accuracy of readings may be inconsistent.
SMBP is contraindicated in these patient populations. Rather, clinicians must remember that these patients’ blood pressure values may vary depending upon where systole occurs during the measurement.41

The most common error in blood pressure measurement is use of an improperly sized cuff. The bladder length recommended by the AHA is 80% of the patient’s arm circumference, and the ideal width is at least 40%.4 See Table 6 for recommended cuff sizes.

For correct cuff placement, the midline of the cuff bladder (commonly marked on the cuff by the manufacturer) should be positioned over the arterial pulsation in the patient’s upper arm following palpation of the brachial artery in the antecubital fossa. For an obese patient whose arm does not easily fit inside a standard cuff, a wrist cuff may be preferable, as long as proper technique is followed.4

Experts from AHA, ASH, and PCNA have recommended that payers cover both the purchase of validated home blood pressure monitors and the time that clinicians spend training patients in SMBP techniques, validating patients’ measurement techniques, interpreting SMBP readings, and providing counseling based on SMBP readings.3

Increasing use of technology has resulted in many mobile blood pressure monitoring devices that can be used with smartphones, tablets, etc. One example of these devices is a mobile arm cuff that plugs directly into a smartphone and, with a downloadable application, can measure and record blood pressure onto the phone. Multiple companies are beginning to market such devices, some of which are FDA approved or validated with the EHS test protocol. Cuffless blood pressure monitoring using heartbeat and pulse data captured with smartphone microphones is another new technology being developed.42 Most of these strategies have not yet been properly validated by international standards. Another type of device that is widely available is the blood pressure kiosk, often found in pharmacies, worksites, and retail stores. Current kiosks may be inaccurate and unreliable.43 These machines allow patients to save their blood pressure readings and track them over time or share them with their clinicians. Such devices could play a large role in SMBP in the future, but current research in this area is limited.
Current Insurance Coverage of Home Blood Pressure Monitors and Additional Support

Insurance benefits for SMBP vary by payer: for example, some payers may cover monitors but not additional support services provided by clinicians. Traditional office-based and fee-for-service models of health care delivery and payment reimburse clinicians only for office-based visits and services (see Table 7). For patients whose insurance does not cover the purchase of home blood pressure monitors, the cost of a monitor may be reimbursed under a health care flexible spending account.44

Conclusion

Clinicians can play an integral role in the widespread implementation of SMBP plus additional clinical support. Clinician support is key to seamlessly integrate SMBP plus clinical support into routine care by changing systems and empowering patients. This guide provides a comprehensive plan and resources for clinicians who want to support SMBP in their practices and health care systems, outlining four categories of evidence-based strategies that clinicians can use to implement a comprehensive SMBP initiative:

▷ Preparing care teams to support SMBP.
▷ Selecting and incorporating clinical support systems.
▷ Empowering patients to use SMBP.
▷ Encouraging coverage for SMBP plus additional clinical support.

By incorporating actions from these strategies into their regular workflow, clinicians can make SMBP plus clinician support a regular part of patient care, which can improve outcomes for patients with hypertension.

<table>
<thead>
<tr>
<th>Coverage Type</th>
<th>Benefits</th>
</tr>
</thead>
</table>
| Medicare Part B (Traditional fee-for-service Medicare) | • Covers ambulatory blood pressure monitoring.3  
• Covers physician interpretation of results for the diagnosis of white coat hypertension.3  
• Does not cover home blood pressure monitors used for SMBP.  
• Does not cover clinician interpretation of readings for treatment of hypertension. |
| Medicare Part C (Medicare Advantage Plans) | • Not mandated, but may cover supplemental coverage of home blood pressure monitors or additional support programs for enrollees.45 |
| Medicaid | • Coverage for home blood pressure monitors and additional support varies by state. |
| Private insurance carriers and self-insured employers | • Decision to cover home blood pressure monitors and additional support is made by each individual plan  
• Some private insurance plans provide these types of benefits only for beneficiaries who are enrolled in disease-management programs for hypertension or other medical conditions that increase the risk of heart disease and stroke.46  
• HCPCS code S9110 can be used by private insurers, but not CMS, for home telehealth reimbursement. |

Appendix A: Proper SMBP Preparation and Technique

Proper patient positioning is important for blood pressure accuracy (Table 8). In addition, exercise, smoking, alcohol consumption, muscle tension, urinary bladder distension, room temperature, and background noise can affect measurement. Table 9 shows the effects of these factors on blood pressure readings.

**Suggested SMBP Measurement Protocol**

To help manage blood pressure for patients with uncontrolled hypertension, clinicians can use SMBP readings to help assess the effects of antihypertensive treatment, including medication changes and lifestyle modifications. Multiple international guidelines suggest that the optimal protocol for obtaining an accurate picture of a patient’s blood pressure using SMBP includes:

- Taking two or three measurements, each 1 minute apart, in the morning and again in the evening.
- Monitoring blood pressure preferably for 7 days and at least for 3 days.
- Recording an average of these measurements.

Guidance on how often well-controlled hypertensive patients should perform regular SMBP as part of long-term follow-up remains a matter of debate. Thus, there is a need for future research on this topic.

**Retraining Clinicians**

To maintain correct blood pressure measurement technique, clinicians must pay careful attention to all steps in the protocol and to retraining. Federally funded multisite clinical trials of hypertension care and control have set the standard for retraining, requiring all blood pressure observers to be retrained at regular intervals. Retraining involves checking a clinician’s competency in several aspects of measurement technique:

- Cuff selection.
- Patient positioning.
- Allowing no talking.
- Accurate auditory or visual observation of the patient’s blood pressure level.

---

**Table 8. Proper Patient Positioning for Blood Pressure Accuracy**

- Have the patient sit quietly for 5 minutes before taking blood pressure.
- Place the cuff on a **bare arm**.
- Use the **proper size cuff**. If two cuff sizes fit, use the larger one.
- Place the artery marker over the **brachial artery**.
- Apply the cuff carefully, allowing room for no more and no fewer than **two fingers** underneath.
- Make sure the patient’s **back is supported and relaxed**.
- Make sure the patient’s **feet are supported and legs are uncrossed**.
- Keep the **upper arm supported, relaxed, and at heart level**.
- Ask the patient the **keep the arm still and not talk** during the measurement.
The American Medical Group Foundation created a toolkit of materials on how to train direct care staff to properly take blood pressure measurements. The toolkit can be found on the group’s Measure Up/Pressure Down website (http://bit.ly/1rwuHao); “Plank 1” includes the following tools for training direct care staff in accurate blood pressure measurement:

- Hypertension Medical Assistant Training
- Checking Blood Pressures Nursing Competency
- Competency Checklist Blood Pressure Measurement
- Competency Checklist Orthostatic Blood Pressure Measurement
- Correct Blood Pressure Measurement Technique Handout
- Blood Pressure Measurement: What Not to Do
- Blood Pressure Measurement: The Proper Way
- New Employee Blood Pressure Measurement Competency Checklist
- Blood Pressure Champion and CDS Education and Auditing Process for New Staff
- Quarterly Blood Pressure Auditing Tool
- Blood Pressure Accuracy and Variability Quick Reference
- Staff Engagement Poster
- Correct Blood Pressure Technique Poster

Implementing an already-investigated model that you believe is promising and feasible for your practice can help reduce heterogeneity in SMBP monitoring and additional support protocols you use. The table below lists examples of additional support interventions that have been successfully implemented in a variety of settings. AHRQ conducted a comparative effectiveness review that included 24 studies; the review found the interventions in 11 of these studies to be effective. Table 10 below includes interventions from four studies rated “quality A”, AHRQ’s highest quality rating, according to the AHRQ’s review methodology; two “quality A” studies were not included because their interventions could not feasibly be translated into clinical practice. Two additional effective studies were published after the AHRQ review; they were deemed “quality A” by two independent reviewers and are thus included in the table. None of the studies found to have ineffective interventions employed the interventions in the table. All studies provided patients with a free, automated, upper arm cuff home blood pressure monitor and proper training on SMBP. Please refer to individual studies for full descriptions of the study populations, interventions, and results.

Appendix C: How to Check a Home Blood Pressure Monitor for Accuracy

The first step in choosing an accurate monitor is to choose one that has passed a formal validation protocol; all SMBP devices sold in the United States meet Food and Drug Administration–required testing standards. However, even a device that has passed an accepted validation test will not provide accurate readings in all patients; the error may be consistently ±5 mmHg in many individuals, especially elderly or diabetic patients. For this reason, clinicians should encourage patients to take any home blood pressure monitor they use to their doctor’s office to measure its accuracy against a mercury sphygmomanometer or comparable device before the readings are accepted. A simple version of the European Society of Hypertension International Protocol has been developed for this purpose and can be done quickly by the physician or other health care clinician and the patient. The following steps to ensure accuracy take approximately 10 minutes:

1. Have the patient sit down with his or her arm at heart level. The arm should be completely relaxed.
2. Allow the patient to rest for 5 minutes.
3. Avoid any conversation during the measurements to prevent an increase in blood pressure.
4. Take a total of five sequential same-arm blood pressure readings, no more than 30 seconds apart.
5. Have the patient take the first two readings with his or her device.
6. The healthcare clinician takes the third reading, preferably with a mercury sphygmomanometer or comparable device.
7. Have the patient take the fourth reading.
8. The fifth and final reading is taken by the healthcare clinician.
9. Compare the difference between the readings from the two cuffs.
10. BP readings will usually decline over the five measurements. The final SBP reading may be as much as 10 mmHg systolic BP lower than the first.
11. If the difference is 5 mmHg or less, the comparison is acceptable.
12. If the difference is greater than 5 mmHg but less than 10 mmHg, do the calibration again.
13. If the difference is greater than 10 mmHg, the device may not be accurate.
14. Repeat this procedure annually. Though there is no established target for how close the readings from the patient’s cuff should be to those from the clinician’s cuff, this exercise can provide a general sense of the SMBP device’s accuracy, which can be taken into consideration for future measurements recorded at home. To further ensure accuracy, consider statically calibrating the clinic and home devices following the National Health and Nutrition Examination Survey (NHANES) Health Tech/Blood Pressure Procedures Manual.
Appendix D: Additional Burden and Cost of Hypertension

Of the 35 million people in the United States with uncontrolled hypertension

- Approximately 13 million are not aware that they have hypertension.
- Approximately 5 million are aware of their hypertension but are untreated.
- Approximately 17 million are aware of their hypertension and are on treatment, but their hypertension is still uncontrolled (see Figure 3).14

Costs of Hypertension

Along with increased cardiovascular morbidity and mortality, hypertension is associated with increased use of health care resources.13 Direct health care costs related to hypertension amount to approximately $131 billion each year.56 Moreover, treatment for cardiovascular disease is estimated to account for 12% of annual spending by both private insurers and Medicaid and for nearly 30% of annual Medicare spending.57

Hypertension-attributable costs are almost 7% of total medical expenditures in the United States.4 A 2007 study using the 2000–2003 Medical Expenditure Panel Survey estimated that the hypertension-attributable cost per person with hypertension was $1,59857:

- $781 per person receiving Medicare.57
- $1,608 per person receiving Medicaid.57
- $845 per person with private insurance.57

The prevalence of untreated and uncontrolled hypertension does not arise from a lack of health care coverage. Of adults with uncontrolled hypertension, more than 28 million have health insurance (see Figure 4), 30 million have a usual source of care, and almost 25 million have been seen by physicians at least twice in the last 12 months.14
Figure 3. Hypertension among Adults in the United States, NHANES 2011–2012.14

- 72 million adults with hypertension
- 35 million adults with uncontrolled hypertension

- 48.1% Controlled
- 51.9% Uncontrolled
- 5.3M Unaware
- 16.7M Aware but untreated
- 12.7M Aware and treated

Figure 4. Distribution of Health Insurance Coverage among Adults (≥18 Years) with Uncontrolled Hypertension, NHANES 2009–2012.14

- 15.2% Medicare
- 40.3% Private insurance
- 7.7% Other public insurance
- 36.9% Uninsured
